AquaNeural — Risk & Governance Framework

Decision controls for a high-dependency technology pilot

Public summary. Exact internal scoring, registers and supporting evidence are intentionally not published.

Risk framework

Risk area	Response approach
Team capability gap	Confirm required technical capability before Phase I procurement
Farmer adoption	Accessible onboarding, training and farmer-facing alert design
Hardware cost volatility	20% contingency reserve and procurement planning
Connectivity / power	Site surveys, edge processing, solar/inverter backup
Pilot underperformance	Predefined gate criteria, monitoring and tuning before decision
Funding / cash flow	Funding thresholds and staged investment gates
AI/CV data scarcity	Local pond data collection and validation before scale-out

Governance model

- RISE acts as Project Sponsor.
- Phase gates control release of subsequent phase budgets.
- The Project Manager maintains the change log, schedule, documentation and risk reporting.
- Scope/cost/schedule changes are evaluated through formal change control.

Pilot decision gate

The source Business Case defines six gate criteria. The gate is intentionally strict: all criteria must be met for a GO decision; an unmet criterion results in NO-GO pending review and remediation.

- Examples include sensor response time, ammonia reduction, power-outage survival, FCR improvement and farmer alert response.

Decision principle

The portfolio evidence is strongest where risk is connected directly to a decision: proceed, pause, remediate, re-baseline or seek a separate investment decision.
